

# Punk Beer Web App

From: [5 Projects To Complete When Starting to Learn Front-End Web Development](#)

**Objective:** Use the punk beer api to create a unique project that uses templating to show data on the page. If you're ambitious, use a front end framework like React.

Build the app in the following order:

- Template data on the page from a generic API request
- Add a search bar, which makes a separate query to a database on request
- Add favourite functionality which allows you to favourite a card
- Create a separate route (using react router) which allows you to see all the beers you've favourited in the session.

Solving these problems one step at a time will help you feel less overwhelmed and more like you're heading in a specific direction.

Lastly, I find it best to eliminate styling from the equation when developing web apps and using a CSS framework. I chose to use Bulma for my example, but there are many options out there for you to explore!
